## 8 Summary

9 The guinea pig spermatozoid nucleus contains actin, myosin, spectrin and cytokeratin. Also, it has been  
10 reported that phalloidin and/or 2,3-butanedione monoxime retard the sperm nuclear decondensation  
11 caused by heparin, suggesting a role for F-actin and myosin in nuclear stability. The presence of an F-  
12 actin/myosin dynamic system in these nuclei led us to search for proteins usually related to this system.  
13 In guinea pig sperm nuclei we detected calmodulin, F-actin, the myosin light chain and an actin-myosin  
14 complex. To define whether calmodulin participates in nuclear-dynamics, the effect of the calmodulin  
15 antagonists W5, W7 and calmidazolium was tested on the decondensation of nuclei promoted by either  
16 heparin or by a *Xenopus laevis* egg extract. All antagonists inhibited both the heparin-extracted and the *X.*  
17 *laevis* egg extract-mediated nuclear decondensation. Heparin-mediated decondensation was faster and  
18 led to loss of nuclei. The *X. laevis* egg extract-promoted decondensation was slower and did not result in  
19 loss of the decondensed nuclei. It is suggested that in guinea pig sperm calmodulin participates in the  
20 nuclear decondensation process.

21 Keywords: Calmidazolium, Heparin, Myosin–actin complex, W7, *Xenopus laevis*

## 22 Introduction

23 The small spermatozoid nucleus is unique in that  
24 it contains a haploid genome and the DNA is  
25 associated to protamines, small highly basic proteins  
26 rich in Arg and Cys (Ward & Coffey, 1991). The  
27 protamine–DNA complex is highly condensed due  
28 to protamine–protamine disulfide bonds (Eddy, 1988;  
29 Yanagimachi, 1988). Once inside the egg, the sperm  
30 chromatin decondenses in order to share its genetic  
31 information (Bezanehtak & Swan, 1999). A clue on  
32 the possible mechanism of chromatin decondensation  
33 was provided by a report indicating that in guinea

pig spermatozoa the nuclear matrix contains actin, 34  
myosin, spectrin and cytokeratin (Ocampo *et al.*, 35  
2005). In addition, the heparin-mediated nuclear 36  
decondensation is retarded by either phalloidin (which 37  
stabilizes F-actin) or by 2,3-butanedione monoxime (a 38  
myosin ATPase inhibitor); these data again suggest that 39  
there is an active actin/myosin system in sperm nuclei 40  
(Ocampo *et al.*, 2005). Other proteins that have been 41  
reported to participate in a motile actin/myosin system 42  
are the myosin light chain kinase (MLCK), calcineurin 43  
and actin (Pujol *et al.*, 1993). 44

Calmodulin (CaM) (17 kDa) is widely distributed 45  
in nature (Stevens, 1982); its 148 aa sequence and 46  
its four Ca<sup>2+</sup>-binding sites are highly conserved 47  
(Tomlinson *et al.*, 1984). CaM controls a large number 48  
of processes, such as fertilization, contraction, motility, 49  
secretion, neurotransmission and metabolism (Stevens, 50  
1982). The dynamics of actin/myosin complexes 51  
are controlled by CaM as follows: the Ca<sup>2+</sup>/CaM 52  
complex activates MLCK by binding near the carboxyl 53  
terminal (Vetter & Leclerc, 2003). The activated MLCK 54  
phosphorylates myosin light chain (MLC) at serine 55  
19 (Adelstein, 1980). Phosphorylated MLC undergoes 56

57 a conformational change resulting in actin/myosin  
58 complex activation (Levinson *et al.*, 2004).

59 In mammalian spermatozoa, CaM has been detected  
60 in the acrosomal and post/acrosomal regions and  
61 in the flagellum (Jones *et al.*, 1980), together with  
62 several CaM binding proteins (Noland *et al.*, 1985).  
63 In guinea pig spermatozoa CaM was observed in  
64 the acrosomal and equatorial regions and along the  
65 flagellum; also, CaM migrates to the post acrosomal  
66 region in acrosome-reacted (AR) spermatozoa (Trejo &  
67 Mújica, 1990; Moreno-Fierros *et al.*, 1992). CaM was also  
68 found in the sperm plasma membrane, in perinuclear  
69 material and in the free vesicles formed during AR  
70 (Hernández *et al.*, 1994). To date, CaM has not been  
71 observed in the nuclei of spermatozoa.

72 In order to determine whether the previously  
73 detected dynamic actin/myosin system has a  
74 physiological role in the sperm nucleus, it is necessary  
75 to search for the presence of proteins known to be  
76 involved in the control of this system. One likely  
77 candidate would be CaM. With this in mind, it was  
78 decided to search for CaM and MLC in the nuclei of  
79 guinea pig spermatozoa. In addition, it was decided to  
80 explore the effect of different CaM antagonists on the  
81 decondensation of spermatozoid nuclei.

## 82 **Materials and methods**

### 83 **Antibodies and reagents**

84 All reagents were of analytical quality. Trizma base, DL-  
85 dithiothreitol (DTT), hexadecyltrimethylammonium  
86 bromide (CTAB), sucrose, HEPES, heparin,  
87 hematoxylin Harris, Hoechst stain solution 33258,  
88 Tween 20, Triton X-100, ATP, nocodazole, cytochalasin  
89 B, glycerol, glycine, 2- $\beta$ -mercaptoethanol, creatine  
90 phosphokinase, cycloheximide, *N*-(6-aminohexyl)-  
91 1-naphthalenesulfonamide hydrochloride (W5),  
92 calmidazolium chloride, *N*-(6-aminohexyl)-5-chloro-  
93 naphthalenesulfonamide hydrochloride (W7),  
94 Coomassie brilliant blue, Ponceau S solution,  
95 human chorionic gonadotropin (HCG), protein A  
96 agarose, ethylenediaminetetraacetic acid (EDTA),  
97 sodium orthovanadate (Na<sub>3</sub>VO<sub>4</sub>), sodium molybdate  
98 (Na<sub>2</sub>MoO<sub>4</sub>), sodium fluoride (NaF), calcium ionophore  
99 A23187, FITC-phalloidin were from Sigma Chemical  
100 Co.; DNase I and Complete™ tablets, a mixture of  
101 protease inhibitors, were bought from Roche; sodium  
102 dodecyl sulfate (SDS) was obtained from BDH;  
103 acrylamide/Bis acrylamide, TEMED, ammonium  
104 persulfate, a protein assay kit, nitrocellulose  
105 membranes and MW markers were from Bio-  
106 Rad; Brij 36-T was from Canamex, S.A.; fat-free milk  
107 was purchased from Baden, S.A.; ethanol, acetone,  
108 methanol, formaldehyde, NaCl, KH<sub>2</sub>PO<sub>4</sub>, MgSO<sub>4</sub>, KCl,

Na<sub>2</sub>HPO<sub>4</sub> and NH<sub>4</sub>Cl were from J.T. Baker; dimethyl 109  
sulfoxide (DMSO), isopropyl alcohol were from Merck; 110  
the enhanced chemiluminescence reagent (ECL) and 111  
immunogold silver staining (IGSS) quality gelatin 112  
were from Amersham; Medium grade LR White resin 113  
kit was bought from London Resin. Cooper grids, 114  
Formvar®, phosphotungstic acid were purchased 115  
from Electron Microscopy Sciences. 116

### *Antibodies* 117

Anti-myosin light chain monoclonal antibodies (Clone 118  
MY-21; cat M4401) were from Sigma Chemical Co. The 119  
anti-actin monoclonal antibody was kindly provided 120  
by Dr Manuel Hernández (Department of Cell 121  
Biology, CINVESTAV-IPN, México). This reagent is 122  
a monoclonal antibody against actin (Diaz-Barriga 123  
*et al.*, 1989) and there after tested in diverse occasions 124  
(Pérez *et al.*, 1994; Pastén-Hidalgo *et al.*, 2008). For 125  
the polyclonal anti-CaM antibody, calmodulin was 126  
obtained from bovine testis and purified by affinity 127  
chromatography as described in Dedman & Kaetzel 128  
(1983). CaM was subjected to SDS-PAGE in the 129  
presence and in the absence of Ca<sup>2+</sup> and the ultraviolet 130  
absorbance spectrum was used to assess CaM purity. 131  
Using the pure CaM preparation, anti-CaM antibodies 132  
were prepared in sheep. Antibodies were purified 133  
by affinity chromatography in a CaM-sepharose 134  
column (Dedman *et al.*, 1978). The antibody titer 135  
was determined by enzyme-linked immunoabsorbent 136  
assay (ELISA). These antibodies have been tested (Trejo 137  
& Mújica, 1990; Hernández *et al.*, 1994). Antibodies 138  
against myosin were produced in rabbit using pure 139  
guinea pig skeletal muscle myosin (Margossian & 140  
Lowey, 1982) and purified by affinity chromatography 141  
on a myosin-sepharose column and titrated by ELISA. 142  
These antibodies have been tested in muscle and in 143  
nuclear matrices, obtaining similar results to those 144  
reported for a commercial antibody (Ocampo *et al.*, 145  
2005). TRITC-labelled secondary goat anti-rabbit, 146  
rabbit anti-sheep, goat anti-mouse antibodies and 147  
horseradish peroxidase (HRP) labelled secondary goat 148  
anti-rabbit and goat anti-mouse antibodies were from 149  
Jackson Immune Research Laboratories, Inc.; G protein 150  
labelled with HRP and gold-labelled were obtained 151  
from Sigma Chemical Co. 152

### **Guinea pig sperm and sperm nuclei isolation** 153

Cauda epididymis and vas deferens spermatozoa were 154  
obtained as in Trejo & Mújica (1990) and centrifuged, 155  
washed twice in 154 mM NaCl at 600g for 3 min 156  
and counted in a Neubauer chamber (Mújica & 157  
Valdes-Ruiz, 1983). Spermatozoa were resuspended 158  
in 50 mM Tris-HCl pH 7.5 (1 × 10<sup>8</sup> cells/ml), 159  
then 100 μl of a commercial mixture of protease 160  
inhibitors (Complete™: one tablet dissolved in 5 ml 161

of distilled water) was added. The sperm suspension was treated with Brij 36-T (Brij spermatozoa) at 1.2% final concentration (Juárez-Mosqueda & Mújica, 1999) and incubated for 5 min on ice, for plasma membrane, nuclear membrane and acrosome solubilization. Brij spermatozoa were collected and washed three times at 600 g for 3 min in 1 ml Tris-Complete™ each time. For nuclei isolation, Brij spermatozoa in Tris-Complete™ were treated with fresh 25.4 mM DTT and incubated for 15 min on ice. In order to solubilize the perinuclear theca-flagellum, 2.22% CTAB (final concentration) was added (Hernández-Montes *et al.*, 1973). The insoluble fraction containing DTT/CTAB nuclei was washed three times in 1 ml Tris-Complete™ as above. Nuclear purity was assessed with a Zeiss optical microscope, Axioscop 2. The DTT/CTAB nuclei were divided: an aliquot was fixed (v/v) in 3% formaldehyde for 1 h and glass slides were prepared for indirect immunofluorescence; a second aliquot was used for western blotting and a third sample was used in decondensation assays.

### 183 Nuclear matrix isolation

184 Nuclear matrices were prepared as described  
185 previously (Ocampo *et al.*, 2005). Briefly,  $1 \times 10^8$   
186 DTT/CTAB-nuclei/ml of Tris-Complete™ pH 7.5,  
187 were mixed with 1 ml of 1 M NaCl and incubated for  
188 30 min on ice twice. Each time, nuclei were collected at  
189 600 g for 3 min and suspended in 1 ml Tris-Complete™.  
190 NaCl supernatants were saved and filtered in 0.45  $\mu$ m  
191 filters and concentrated (3500 g for 50 min at 4 °C) in  
192 Amicon ultratubes. Nuclei were resuspended in 1 ml  
193 Tris-Complete™ ( $35 \times 10^6$  nuclei/ml), 5 IU heparin  
194 and incubated at 37 °C for 1 min. Then the sample was  
195 diluted with 2 ml Tris-Complete™ and centrifuged  
196 (600 g for 3 min). Supernatants were passed through  
197 0.45  $\mu$ m filters and concentrated as before. Heparin-  
198 treated nuclei were incubated for 30 min in 1 ml Tris-  
199 Complete™ ( $1 \times 10^8$  nuclei/ml), 50 IU DNase I,  
200 10 mM MnCl<sub>2</sub> at 37 °C. Nuclei were collected at 600 g  
201 for 3 min for a second DNase I treatment; supernatants  
202 were processed as above. The pellet (sperm nuclear  
203 matrices) from  $1 \times 10^8$  nuclei was resuspended in  
204 1 ml Tris-Complete™, solubilized with 0.5% SDS (final  
205 concentration) and protein was concentrated as above.  
206 After filtration (0.45  $\mu$ m membrane), all samples were  
207 concentrated in Amicon ultratubes at 3500 g for  
208 50 min at 4 °C. Protein concentration was de-  
209 termined as in Lowry *et al.*, (1951). Samples  
210 were used for electrophoresis and western blot-  
211 ting.

### 212 SDS-PAGE and western blotting

213 DTT/CTAB nuclei, nuclear matrices suspended in  
214 Tris-Complete™ and supernatants from the different

solutions used to obtain the nuclear matrices were 215  
collected. All samples were diluted with 0.5 volume 216  
sample buffer (500 mM Tris pH 6.8, 10% glycerol, 217  
10% SDS, 0.05% 2- $\beta$ -mercaptoethanol and 0.01% 218  
bromphenol blue) and boiled for 5 min (Laemmli, 219  
1970). Samples were subjected to electrophoresis in 220  
15% polyacrylamide-SDS gels and transferred to 221  
nitrocellulose membranes (Towbin *et al.*, 1979). CaM 222  
transfer was done at 4 °C for 20 h at 20 volts. 223  
The buffer used was: 25 mM potassium phosphate 224  
(pH 7), 25 mM sodium phosphate (pH 7), 12 mM 225  
Tris, 192 mM glycine, 20% methanol (Hincke, 1988). 226  
Nitrocellulose membranes were immunostained as 227  
previously described (Moreno-Fierros *et al.*, 1992). 228  
Antibodies were appropriately diluted with blocking 229  
solution, containing 5% fat-free milk in TBS-T (150 mM 230  
NaCl, 100 mM Tris-HCl pH 7.6 plus 0.1% Tween 231  
20). Primary antibodies used were: anti-calmodulin 232  
(1:100) and anti-myosin light chain (1:200). HRP- 233  
labelled secondary antibodies were diluted 1:4000 in 234  
blocking solution. Three controls were: (a) sample 235  
stained without the primary antibody, only with 236  
the secondary antibody; (b) sample incubated with 237  
preimmune sera instead of the primary antibody; and 238  
(c) for CaM an additional control was to incubate 239  
the antibody with a 10-fold molar excess purified 240  
CaM. HRP was developed by chemiluminescence ECL 241  
kit. 242

### Immunoprecipitation 243

Protein A-agarose (5  $\mu$ l) was incubated with 0.4  $\mu$ g 244  
anti-myosin antibody for 5 min at 4 °C. Then, 1 mg 245  
nuclear matrix sperm protein (see above) was added. 246  
The mixture was kept overnight at 4 °C under constant 247  
agitation. Antibody-protein complexes were recovered 248  
by centrifugation (5000 g for 5 min). Then, the samples 249  
were washed two times with RIPA buffer (20 mM 250  
Tris-HCl, 316 mM NaCl, 2 mM EDTA, 20 mM sodium 251  
orthovanadate, 20 mM sodium molybdate, 50 mM 252  
sodium fluoride and 1% Triton X-100, pH 7.5). The 253  
pellet was resuspended in 50 mM Tris-HCl pH 7.5 254  
(50  $\mu$ l) plus 25  $\mu$ l of Laemmli sample buffer and boiled 255  
for 5 min (Laemmli, 1970). Protein was subjected to 256  
electrophoresis in 10% polyacrylamide-SDS gels and 257  
transferred to nitrocellulose membranes for western 258  
blotting (see above). The primary antibody was anti- 259  
actin, appropriately diluted (1:100) with blocking 260  
solution: 5% fat-free milk in TBS-T. HRP-labelled 261  
appropriate secondary antibody (1:4000) was used. 262  
HRP was developed by chemiluminescence ECL kit. As 263  
a positive control of the myosin-actin interaction, we 264  
used muscle extract. The muscle extract was prepared 265  
from guinea pig skeletal muscle as described above for 266  
myosin antibodies. 267

|     | <i>Preparation of egg extracts from X. laevis</i>                     | 356 |
|     | Extracts from <i>X. laevis</i> eggs were obtained as described        | 357 |
|     | by Hutchinson <i>et al.</i> , (1988) with slight modifications.       | 358 |
|     | At three month intervals mature frogs were stimulated                 | 359 |
|     | to lay eggs by a first injection of 100 IU human                      | 360 |
|     | chorionic gonadotropin into their dorsal lymph sacs,                  | 361 |
|     | then after 5 h a second injection of 500 IU human                     | 362 |
|     | chorionic gonadotropin was performed; 17 h later                      | 363 |
|     | the eggs were harvested. Eggs were collected in                       | 364 |
|     | saline water (110 mM NaCl) at 21 °C and then                          | 365 |
|     | incubated in de-jellying solution (5 mM DTT, 110 mM                   | 366 |
|     | NaCl, 20 mM Tris-HCl, pH 8.5) for 5 min. Following                    | 367 |
|     | removal of the jelly coats, the eggs were rinsed three                | 368 |
|     | times in saline and examined. Eggs were activated with                | 369 |
|     | the Ca <sup>2+</sup> ionophore A23187 (5 $\mu$ g/ml) for 5 min (Blow  | 370 |
|     | & Laskey, 1986). Next, the eggs were rinsed twice in                  | 371 |
|     | ice-cold extraction buffer (110 mM KCl, 5 mM MgCl <sub>2</sub> ,      | 372 |

20 mM HEPES (pH 7.5), 2 mM 2- $\beta$ -mercaptoethanol containing protease inhibitors (Complete<sup>TM</sup> 100  $\mu$ l/ml). Excess buffer was removed from the egg suspension and the sample was centrifuged at 10000 *g* for 20 min at 4 °C. After centrifugation a stratified extract was obtained consisting of a yolk pellet, a soluble phase and a lipid cap. The soluble phase was removed and mixed with cytochalasin B (50  $\mu$ g/ml final concentration). This material was centrifuged a second time as above. Samples were stored at -70 °C in the presence of Complete<sup>TM</sup> (protease inhibitor mixture), plus 5% glycerol and used for activation by ATP treatment.

#### ATP treatment of egg extracts

The egg extracts (1 ml) were mixed with 0.15 volume of ELB (1 mM DTT, cycloheximide (1  $\mu$ g/ml), 250 mM sucrose) and nocodazol (1:500). The mixture was centrifuged at 10 000 *g* for 20 min at 4 °C. Next, 1 mM ATP, 20  $\mu$ l/ml PC (10 mM sodium phosphate, pH 7) and 1  $\mu$ l/ml creatin kinase (50  $\mu$ g/ml) were added and incubated for 5 min (Leno & Laskey, 1991). Egg extracts were used for nuclear decondensation.

#### Nuclear decondensation assay

DTT/CTAB nuclei,  $18 \times 10^6$ /ml in 50 mM Tris pH 7.5 were treated or not with 100  $\mu$ M W5, 100  $\mu$ M W7 or 10  $\mu$ M calmidazolium for 30 min at room temperature. Then samples were subjected to centrifugation at 600 *g* for 3 min and the pellet was resuspended in 1 ml of treated egg extract (see above). These samples were incubated at 37 °C and aliquots were withdrawn at 1, 3, 6, 10, 30, 120 and 240 min, fixed (v/v) and stained with: 8  $\mu$ g/ml Hoechst 33258, 7.4% formaldehyde, 200 mM sucrose, 10 mM HEPES, pH 7.6. From each sample, smears were prepared on glass slides and observed in an Olympus IX70 microscope,  $\times 1000$  magnification and micro-photographed with a digital camera (Color View 12) and captured using the software Imaging System AnalySIS 3.0 GmbH, for morphometric analysis.

#### Morphometric analysis

Nuclei morphometric analysis was performed with the software Imaging System AnalySIS 3.0 GmbH. The evaluated parameters were area and diameter. Comparisons between treatments were performed by unpaired *t*-test. All results are representative of at least three different experiments. Results comparing three replicates are expressed as the mean  $\pm$  standard deviation. In each determination 40 heparin-treated nuclei or 40 egg extract treated nuclei were evaluated. Significance levels for both were set at  $p < 0.001$ .

## Results

### In guinea pig sperm calmodulin was detected in whole nuclei and in the nuclear matrices

Highly purified, membrane-free nuclei were obtained by spermatozoid treatment with DTT/CTAB, followed by extensive washing. Then, the nuclear matrices were isolated using sequential protein extraction treatments: (1) high NaCl concentration; (2) heparin; and (3) DNase I. The proteins extracted after each different treatment, as well as those retained in either whole nuclei or nuclear matrices, were analysed by SDS-PAGE, transferred to nitrocellulose membranes and subjected to western blotting using CaM antibodies; these antibodies detected a 17 kDa protein (Fig. 1A). CaM was detected in whole nuclei (Fig. 1A, lane 1) and in the isolated nuclear matrices (Fig. 1A, lane 7). Two positive CaM controls were used: testis homogenate (Fig. 1A, lane 2) and pure CaM (Fig. 1A, lane 3). In the extracted proteins, CaM was detected only after the DNase I treatment (Fig. 1A, lane 6). In contrast, CaM was not detected in the nuclear NaCl extracts (Fig. 1A, lane 4) or in the heparin extracts (Fig. 1A, lane 5). Thus, CaM remained associated to the nuclear matrix even after diverse extraction procedures, suggesting that it was not a contaminant from the cytosol. In a silver-stained gel, it was observed that both the NaCl and the heparin treatment extracted some proteins from the nucleus (Fig. 1B, lanes 4 and 5, respectively). The antibody specificity was confirmed as follows: (1) a competitive inhibition assay, where the anti-CaM antibody was treated with 10-fold molar excess of purified CaM did not show any bands (Fig. 1C); (2) omission of the primary antibody resulted in absence of any band (data not shown); or (3) using preimmune serum instead of the primary antibody which was negative too (data not shown).

CaM was also detected in DTT/CTAB nuclei by indirect immunofluorescence and confocal microscopy projection (Fig. 1D, a). CaM was observed in whole nuclei as a fine granulated fluorescence. In optical sections, in the middle of the nucleus, CaM gave the same image (Fig. 1D, b). The negative controls were: (1) samples in which the primary antibody was omitted (Fig. 1E, a), no fluorescence was observed; phase contrast image (Fig. 1E, b); (2) the primary antibody was competed with an excess (10 fold) of pure CaM protein; or (3) preimmune serum was used instead of the primary antibody, none of the negative controls exhibited fluorescence (data not shown).

Nuclear matrices were subjected to immunogold staining using a polyclonal anti-CaM antibody. Heavy labelling of the nuclear matrix was observed (Fig. 2A). The negative control was a sample in which the primary antibody was omitted and showed severe reduction of

**Figure 1** Calmodulin (CaM) identification in guinea pig sperm nuclei by western blotting and indirect immunofluorescence. (A) Positive expression of CaM was observed in whole nuclei sperm proteins (lane 1). Also, in the positive controls: mouse testis (lane 2), pure CaM (lane 3). Nuclear proteins extracted with: DNase I (lane 6) and nuclear matrices (lane 7). No expression of CaM was observed in NaCl (lane 4) and heparin (lane 5) extracted proteins; although positive proteins bands were detected in silver stained gel (B). (C) Negative control; not immunoreactive band was detected in samples assayed (lanes 1–7) when the first antibody was competed with a 10 fold molar excess of pure CaM. (D) Immunolocalization of CaM in whole nuclei (DTT/CTAB) of guinea pig sperm, confocal microscopy image (projection) (a) and optical sections (b). (E) Negative control; nuclei were treated without the first antibody, no fluorescence was observed (a). Phase contrast image (b). Bar: 8 μm.

477 the gold label (Fig. 2B). In addition, when thin sections  
 478 of whole sperm cells were immunogold stained, CaM  
 479 was revealed within the nucleus and to a lesser extent  
 480 elsewhere (Fig. 2C).

#### 481 **Guinea pig sperm nuclei contain F-actin and the** 482 **myosin light chain**

483 In DTT/CTAB nuclei, F-actin was observed by confocal  
 484 microscopy after staining with FITC-phalloidin  
 485 (Fig. 3A, a). In optical sections, the same fluorescence  
 486 image was observed (Fig. 3A, b). MLC was also  
 487 detected by indirect immunofluorescence and confocal  
 488 microscopy (Fig. 3B, a). The image exhibits granulated  
 489 fluorescence throughout the nucleus. In optical  
 490 sections, the same granulated fluorescence was  
 491 observed (Fig. 3B, b). In negative controls, in which  
 492 the primary antibody was omitted or incubated with  
 493 preimmune serum instead of the primary antibody,  
 494 no fluorescence was observed (Fig. 3C, a); we also  
 495 include phase contrast image of the same sample  
 496 (Fig. 3C, b).

497 The presence of MLC in DTT/CTAB nuclei was  
 498 confirmed by western blotting (Fig. 3D, lane 2). As

with the positive control, testis homogenate (Fig. 3D, 499  
 lane 1) was used. In both the control and the sample, 500  
 the anti-MLC antibody detected a wide band spanning 501  
 from 17 to 20 kDa, which is in the range specified by 502  
 the manufacturer (Sigma Chemical Co.) and expected 503  
 for MLC (Wagner, 1982). In a negative control in 504  
 which the primary antibody was omitted, no bands 505  
 were detected (Fig. 3E) in nuclear proteins (lane 2) 506  
 neither testis homogenate (lane 1). A second negative 507  
 control was done with preimmune sera instead of the 508  
 primary antibody, it give also a negative result (data not 509  
 shown). 510

#### 511 **Actin-myosin interaction was observed in guinea** 512 **pig sperm nuclei matrices**

513 Guinea pig spermatozoid nuclei contain actin and 514  
 myosin (Ocampo *et al.*, 2005). The interaction between 515  
 these proteins would be a strong indication that they 516  
 play a physiologic role in nuclei. To test this hypothesis, 517  
 an SDS-extract from nuclear matrices was treated 518  
 with an anti-myosin antibody plus protein A agarose. 519  
 The immunoprecipitate was subjected to SDS-PAGE, 520  
 transferred to a nitrocellulose membrane and analysed

**Figure 2** Immunogold detection of CaM in nuclear matrices and whole sperm cells. Nuclear matrices were treated with anti-CaM antibodies. Appropriate gold-labelled (5 nm particles) G-protein was used. (A) CaM detection was abundant in the nuclear matrices. (B) Negative control, nuclear matrices incubated only with G-protein, where no immunogold staining was detected. Bars: 200 nm. (C) Thin sections from guinea pig spermatozoa embedded in LR White resin incubated with anti-CaM antibodies, the image shows positive CaM detection inside nuclei. Bar: 500 nm.

521 with an anti-actin antibody. A 37–50 kDa protein band  
 522 was detected (Fig. 4, lane 1), indicating that actin  
 523 co-precipitated with myosin. In supernatants of the  
 524 immunoprecipitate no bands were detected (Fig. 4, lane  
 525 2). In the muscle extract used as a control, a band of 45  
 526 kDa was revealed by the anti-actin antibody (Fig. 4,  
 527 lane 3) also in whole nuclei spermatozoa a band of 45  
 528 kDa was detected (Fig. 4, lane 4). Negative controls  
 529 performed without the primary antibody or without  
 530 the primary antibody but in the presence of preimmune  
 531 sera, did not show positive bands (Fig. 4, lane 6); an  
 532 additional control was performed incubating nuclear  
 533 matrix extracts with Protein A agarose alone (without  
 534 anti-myosin antibody) and revealed for actin. Under  
 535 these conditions no bands were detected (Fig. 4, lane  
 536 5).

### 537 **The heparin-mediated sperm nuclei decondensation** 538 **is inhibited by CaM antagonists**

539 In order to define whether CaM participates in nuclear  
 540 decondensation, we measured the effect of different  
 541 CaM antagonists (W5, W7 and calmidazolium in  
 542 DMSO) on the heparin-mediated nuclear decondensa-  
 543 tion. The diluent (DMSO) plus heparin was assayed  
 544 as a control. Non treated nuclei remained stable up

545 to 240 s (Fig. 5, ●) heparin promoted significant nuclei  
 546 decondensation at 20 s ( $p < 0.001$ ) and a further increase  
 547 was observed to become stable at 240 s (Fig. 5, ■).  
 548 Calmidazolium inhibited decondensation completely  
 549 (Fig. 5, □). Decondensation was evaluated at 60 up  
 550 to 240 s after heparin addition measuring the area  
 551 (Table 1) and diameter (data not shown) of individual  
 552 nuclei. Before treatment, the mean area of the  
 553 nuclei was  $73.61 \mu\text{m}^2$  and the highest stable decon-  
 554 densation was  $109.38 \mu\text{m}^2$ . All the CaM antagonists  
 555 were effective inhibitors of nuclear decondensa-  
 556 tion.

557 After longer incubation times, heparin treated  
 558 sperm nuclei disappeared from view, which probably  
 559 indicates that nuclear structures became unstable  
 560 (Fig. 6), such that after 10 min of heparin treatment,  
 561 the original  $6.3 \times 10^6$  sperm nuclei decreased to  
 562  $1.3 \times 10^6$  nuclei. An 80% decrease. This was not  
 563 mediated by proteases, as addition of Complete<sup>TM</sup>  
 564 (a mixture of protease inhibitors) did not prevent  
 565 nuclei disappearance (data not shown). In contrast,  
 566 in the presence of the CaM antagonists, the heparin-  
 567 mediated loss of sperm nuclei remained low, at about  
 568 20%; sperm nuclei numbers were as follows: in the  
 569 presence of: W5,  $5.7 \times 10^6$ ; W7,  $5.3 \times 10^6$  and  
 570 calmidazolium  $5.7 \times 10^6$  (Fig. 6). Thus, it seems that

**Figure 3** In guinea pig sperm whole nuclei: F-actin localization by FITC-phalloidin stain and myosin light chain (MLC) localization and identification by indirect immunofluorescence and western blotting. (A) Confocal microscopy image (projection) showing F-actin in whole DTT/CTAB nuclei of guinea pig sperm (a) and optical sections (b). (B) Confocal microscopy image (projection) showing the immunolocalization of MLC in whole nuclei of guinea pig sperm (a) and optical sections (b). (C) Negative control; nuclei were treated with preimmune sera instead the first antibody, no fluorescence was observed (a). Phase contrast image (b). Bar: 8  $\mu$ m. D: DTT/CTAB nuclei positive expression of MLC is shown. Lane 1: positive control (mouse testis); lane 2: nuclear sperm proteins of guinea pig. (E) Negative control; not immunoreactive band was detected when the first antibody was omitted.

571 in addition to inhibiting decondensation, or perhaps  
 572 as a consequence of this inhibition, CaM antagonists  
 573 also inhibit the heparin-promoted loss of sperm  
 574 nuclei.

575 **The *Xenopus laevis* egg extract-mediated**  
 576 **decondensation of sperm nuclei is inhibited by**  
 577 **different CaM antagonists**

578 The heparin decondensation method suggested that  
 579 CaM participates in nuclear decondensation. To further  
 580 analyse this possibility, we decided to test a second  
 581 method to decondense nuclei which is perhaps more

582 physiological: the *X. laevis* egg extract-mediated sperm  
 583 nucleus decondensation. In this model, we also tested  
 584 the effect of each of three different CaM antagonists:  
 585 W5, W7 and calmidazolium in DMSO. The results  
 586 were different to those obtained with heparin because  
 587 the *X. laevis* extract promoted a much lower rate of  
 588 decondensation and in addition treated nuclei did  
 589 not disappear, even at very long incubation times. In  
 590 the non-treated controls, nuclei remained stable up  
 591 to 240 min of experimentation (Fig. 7, ●). In nuclei  
 592 treated with the *X. laevis* extract, nuclei remained  
 593 stable for up to 6 min of incubation; then, at 10 min  
 594 significant decondensation ( $p < 0.001$ ) was observed

**Table 1** Heparin-mediated decondensation of sperm nuclei. Effect of calmodulin antagonists W5 (100  $\mu$ M), W7 (100  $\mu$ M) and calmidazolium (10  $\mu$ M).

| DTT/CTAB Nuclei treatment | Area of individual nuclei ( $\mu\text{m}^2$ ) / Duration of treatment (s) |                    |                    |                    |

DTT/CTAB nuclei ( $35 \times 10^6$ /ml) in 50 mM Tris pH 7.5, were incubated for 30 min with calmodulin antagonists (or without) or DMSO (antagonist's diluent); then added with 5 IU heparin. At zero time and after 60, 120 and 240 s heparin treatment, samples were fixed with 1.5% formaldehyde in PBS (final concentration). Smears from each sample were stained on glass slides and subjected to morphometric analysis (See Materials and methods). All results are representative of at least three different experiments. Data are the means  $\pm$  standard deviation of three replicates.

\* $p < 0.001$  vs non-heparin-treated nuclei.

\*\* $p < 0.001$  vs heparin or DMSO/heparin-treated nuclei.

**Figure 4** Myosin association to actin in the nuclear matrix of guinea pig spermatozoa. Nuclear matrices were dissolved in 0.5% SDS and immunoprecipitated (IP) using anti-myosin antibody. The precipitate and the supernatant were electrophoresed and analyzed by Western blotting with anti-actin antibodies. Lane 1: nuclear matrices (IP); lane 2: supernatant (IP); lane 3: muscle homogenate (positive control); lane 4: whole nuclei; lane 5: negative control incubating nuclear matrices extract with protein A agarose, but without anti-myosin antibody and lane 6: negative control without the primary antibody, actin was not detected.

**Figure 5** Rate of heparin-mediated nuclei decondensation in the presence and in the absence of the calmodulin antagonist calmidazolium (10  $\mu$ M). Reaction mixture as in Table 1. Aliquots were taken at the times indicated in the figure. Nuclear decondensation was evaluated up to 240 s of treatment. From 20 s onwards heparin promoted significant (\* $p < 0.001$ ) nuclei decondensation. ● Without heparin, ■ heparin and □ heparin/calmidazolium.

595 which increased up to 2 h and then remained constant  
596 (Fig. 7, ■). Calmidazolium inhibited decondensation  
597 (Fig. 7, □).

598 Other CaM antagonists were tested; it was observed  
599 that each CaM antagonist inhibited the *X. laevis* extract-  
600 mediated nuclear decondensation, as determined by  
601 measuring the area (Table 2) and diameter (data not  
602 shown) of individual nuclei at 10 up to 240 min. The  
603 highest decondensation value was observed at 120 min  
604 of treatment, where an area of 125.42  $\mu\text{m}^2$  was  
605 measured. The CaM antagonist sensitivity of the egg  
606 extract-mediated nuclear decondensation indicated  
607 that this process is mediated by CaM. In addition,  
608 it was observed that the egg extract treatment

609 did not cause disappearance of decondensed sperm  
610 nuclei.

## 611 Discussion

612 When the  $\text{Ca}^{2+}$  concentration increases in a given  
613 cell compartment, four  $\text{Ca}^{2+}$  ions bind to calmodulin  
614 (CaM) activating it. Then, the  $4\text{Ca}^{2+}/\text{CaM}$  complex  
615 binds and activates the myosin light chain kinase  
616 (MLCK). Activated MLCK phosphorylates the myosin  
617 light chain (MLC) at serine 19. Once activated, myosin  
618 binds F-actin, forming a dynamic, motile system  
619 (Adelstein, 1980; Sellers, 2000). The MLCK-mediated

**Figure 6** Number of DTT/CTAB sperm nuclei remaining after heparin treatment in the presence and in the absence of calmodulin antagonists. Three independent experiments were performed. Data are the means from samples fixed at 4 and 10 min of heparin treatment. \* $p < 0.001$  vs sample without heparin. \*\* $p < 0.001$  vs Tris/heparin or DMSO/heparin. CDZ, calmidazolium.

**Figure 7** Rate of *Xenopus laevis* egg-extract-mediated nuclei decondensation in the presence and in the absence of the calmodulin antagonist calmidazolium (10  $\mu$ M). Reaction mixture as in Table 2. Aliquots were taken at the times indicated in the figure. Nuclear decondensation was evaluated up to 240 min of treatment. From 10 min onwards *X. laevis* egg-extract promoted significant (\* $p < 0.001$ ) nuclei decondensation. ● Without egg extract, ■ egg extracts and □ egg extract/calmidazolium.

620 MLC phosphorylation produces a conformational  
621 change in the actin/myosin complex, which in turn  
622 causes contraction (Stull *et al.*, 1993).

623 In non-muscle cells, actin/myosin complexes are  
624 involved in processes such as cytokinesis and  
625 migration (Adelstein *et al.*, 1980). In the nuclei of  
626 different cell types, CaM is involved in a number of  
627 functions such as DNA replication and repair (Vendrell  
628 *et al.*, 1991). The presence of CaM-binding proteins in  
629 the nucleus of neural cells has been observed (Pujol  
630 *et al.*, 1993). Also, in rat-hepatocyte nuclei, proteins  
631 such as MLCK, caldesmon, spectrin and actin have

632 been detected and their presence indirectly suggests  
633 that CaM might participate in nuclear decondensation  
634 (Bachs *et al.*, 1990).

635 Our group reported that: (a) in guinea pig sperm  
636 nuclei, there are cytoskeleton proteins (spectrin and  
637 cytokeratin) and CaM binding proteins (actin and  
638 myosin); and (b) actin and myosin participate in the  
639 heparin-mediated decondensation of nuclei (Ocampo  
640 *et al.*, 2005). Here, CaM was detected in the whole  
641 nucleus and in the nuclear matrix of guinea pig sperm  
642 (Figs. 1 and 2). The 17 kDa band revealed has a MW  
643 similar to that previously reported (Crivici & Ikura,  
644 1995; Putkey *et al.*, 2003). CaM is deeply embedded  
645 in the nucleus, strongly suggesting that this is not  
646 a cytoplasmic contaminant. That is, after thorough  
647 washing, pure DTT/CTAB nuclei retained CaM, which  
648 was not released by either the NaCl treatment or  
649 the heparin treatment. Only the DNase I treatment  
650 succeeded in partially extracting CaM from the nuclear  
651 matrices.

652 To assess the physiological role of CaM in  
653 nuclei, we followed the effect of different CaM  
654 antagonists (W5, W7 and calmidazolium) on two  
655 nuclear decondensation models: (a) heparin (Table 1  
656 and Fig. 5); and (b) *X. laevis* egg extracts (Table 2  
657 and Fig. 7). Heparin has been suggested to  
658 promote decondensation by competing with DNA  
659 for protamines (Bertanzon *et al.*, 1981). Egg extracts  
660 have been reported to cause nuclei decondensation,  
661 probably mimicking the physiological process with  
662 more accuracy (Lohka & Masai, 1983). CaM  
663 antagonist inhibited decondensation by either the  
664 heparin or the egg extract with a value of  $p <$   
665 0.001.

**Table 2** *Xenopus laevis* egg extract-mediated decondensation of sperm nuclei. Effect of calmodulin antagonists W5 (100  $\mu$ M), W7 (100  $\mu$ M) and calmidazolium (10  $\mu$ M).

| Calmidazolium/egg extract | 76.14 $\pm$ 2.77  | 86.68 $\pm$ 9.63**  | 79.41 $\pm$ 11.46** | 79.51 $\pm$ 5.51**  | 78.92 $\pm$ 12.35** |

DTT/CTAB nuclei ( $18 \times 10^6$ /ml) in 50 mM Tris pH 7.5 were incubated for 30 min with (or without) calmodulin antagonists or DMSO (antagonists diluent). Nuclei were washed and further incubated in 1 ml *Xenopus laevis* activated egg extract for zero, 10, 30, 120 and 240 min and fixed. Samples were stained and morphometric nuclei analysis was done as indicated in Materials and Methods. All results are representative of at least three different experiments. Data are the means  $\pm$  standard deviation of three replicates.

\* $p < 0.001$  vs non-extract-treated nuclei.

\*\* $p < 0.001$  vs egg extract-treated nuclei or DMSO/egg extract-treated nuclei.

The egg extract-mediated decondensation is perhaps more physiological. This idea would explain the high stability observed in the decondensed nuclei, which in the heparin model were highly unstable (Fig. 6). The nuclei loss observed in the heparin-treated samples was not mediated by proteases, as addition of a protease inhibitor mixture (Complete<sup>TM</sup>, Roche) did not protect the nuclei.

The identification of actin in several nuclear complexes has led to suggestions that it participates in diverse nuclear activities including chromatin remodelling (Olave *et al.*, 2002), transcription (Philimonenko *et al.*, 2004) and nucleocytoplasmic traffic (Bettinger *et al.*, 2004). However, in the cell nucleus no F-actin had been detected leading to suggestions that actin forms only short filaments (Pederson & Aebi, 2003). However, we did detect F-actin in isolated whole nuclei (DTT/CTAB nuclei) from guinea pig spermatozoa (Fig. 3A). We also detected MLC in the whole nucleus (Fig. 3B, D) and identified an interaction of actin with myosin in the nuclear matrix (Fig. 4). Thus, it may be proposed that in the guinea pig sperm nucleus there is a complete contractile actin/myosin system, where CaM would activate nuclei decondensation through phosphorylation of MLC.
